# A piece of my pie- budgeting and profit 

analysis

## Teacher notes

The business of farming does not involve only the physical planting and harvesting of a crop. Farmers undertake many roles and being a good business manager is important to ensure a successful enterprise. Successful businesses make a profit and in farming profit can be measured using the following equation
(Yield x Price) - Costs = Profit

- Yield - how much a farmer grows or produces
- Price - what the farmer is paid for the crop he grows
- Cost - how much it costs to grow the crop
- Profit - what is left after costs are paid.

Cereal farmers make money by selling the grain they produce, but it is difficult for a farmer to know exactly how much grain they will grow as it is very dependent on seasonal conditions. It is also not unusual for the price paid for grain to fluctuate considerably over the year. The table below outlines some of the variables that affect a farmer's profitability.

| Variables |  |  |
| :---: | :---: | :---: |
| Yield can be affected by: | Price can be affected by: | Costs can be affected by: |
| Rainfall | Global markets | Global markets |
| Soil type | Marketing decisions | Amount of inputs (e.g. <br> fertiliser) |
| Inputs (e.g. fertiliser and <br> chemical) | Quality of product | Investment decisions |
| Technology inputs | Time of marketing | Outsourcing of work <br> (seeding or harvesting) |

Adapted from Plan, Prepare, Prosper. DAFWA 2011.
Profitable cereal growing requires high production and low costs. All input decisions like chemical and fertiliser are based on the benefit to the yield and quality potential of the crop. Farmers use many tools to guide their decision making. Having clear projections of yields and potential selling price points helps them to manage the costs of production and understand the financial consequences of market fluctuations and seasonal variation.

## Reflection

Farmers undertake many roles but often outsource work to specialists. In the students activities provided the farmer has an agronomist, a grain marketer and a farm advisor working for him. What services do they provide?

Agronomist: Advises on growing the crop, for example chemical, fertiliser, new seed varieties, inputs, timing of seeding and harvesting. Has a science background.

Grain marketer: Assists with planning and executing marketing strategies. They analyse markets, identify trends and suggest which companies the farmer should sell the wheat to get the best price. These people may have a science, business or agriculture degree, and are broadly interested in world commodity markets and future trends.

Farm advisor: Assists with the financial management of the business, such as planning the amount of land to seed with crops, new machinery the farmer could purchase, preparing yearly budgets and reviewing how profitable the business has been on a year to year basis. Often have an economics or management degree.

## Budgeting and profit analysis assignment

Farmer Black planted 800ha of wheat this season. She works to produce maximum yields for minimum costs knowing that seasonal variability can affect her yields and global markets can change the price she is paid for her grain.

This season had average seasonal conditions and she received a good price for her grain. You need to assess her profitability.

Profit can be measured by the equation below:
(Yield x Price) - Costs = Profit.
The components of profit for a grain enterprise are:
Yield - how much grain a farmer produces
Price - what the farmer is paid for the grain produced
Cost - how much it costs to grow the crop
Profit - what is left after the costs are paid
Income - total money received for grain from buyer.

1. Farmer Black averaged 2.6 tonnes per hectare ( $\mathrm{t} / \mathrm{ha}$ ) over her 800 ha crop. What was her total yield?

## 2.6t $\mathrm{X} \mathrm{800ha}=2080 \mathrm{t}$

2. She sold her grain for $\$ 311$ per tonne. What was her total income from selling the grain?

## $2080 \times \$ 311$ = \$646 880

3. To use the equation, you also need to know the costs of growing and delivering the crop. The table below shows the input costs that were budgeted. The growing costs remain the same, regardless of yield and are calculated per hectare. Delivery costs are directly related to how much is harvested and are worked out on a per tonne basis.

| Inputs | Cost | $\$$ |
| :--- | ---: | ---: |
| Seed | $30 / \mathrm{ha}$ | $\mathbf{2 4 0 0 0}$ |
| Fertiliser | $148 / \mathrm{ha}$ | $\mathbf{1 1 8 4 0 0}$ |
| Chemical | $73 / \mathrm{ha}$ | 58400 |
| Fuel | $35 / \mathrm{ha}$ | $\mathbf{2 8 0 0 0}$ |
| Crop Insurance | $2 / \mathrm{ha}$ | $\mathbf{1 6 0 0}$ |
| Grain Marketing | $1 / \mathrm{ha}$ | $\mathbf{8 0 0}$ |
| Agronomy | $1 / \mathrm{ha}$ | $\mathbf{8 0 0}$ |
| Farm Advisor | $1 / \mathrm{ha}$ | $\mathbf{8 0 0}$ |
| Wages | $22 / \mathrm{ha}$ | $\mathbf{1 7 6 0 0}$ |
| Freight | $10 / \mathrm{t}$ | $\mathbf{2 0 8 0 0}$ |
| Receival Fees | $10.2 / \mathrm{t}$ | $\mathbf{2 1 2 1 6}$ |
| Destination Freight Fee | $18.6 / \mathrm{t}$ | $\mathbf{3 8 6 8 8}$ |
|  |  | $\mathbf{\$ 3 3 1 1 0 4}$ |

Note: All calculations based on an average yield of 2.6t/ha
4. Use the equation (Yield x Price) - Costs = Profit to work out this year's profit.
(2080 X 311) - $331104=$ Profit
$646880-331104=315776$

Profit = \$315 776
5. Create a pie chart to illustrate how much of her income she got to keep and how much was paid to her suppliers and service providers.

6. Can you recommend ways that Farmer Black can increase her 'piece of the pie' next season? Consider yield, price and cost...

Improving yield by adding fertiliser
Waiting for a better price
Reducing costs
Focusing on marketing so she sells the wheat to the buyer who will offer the best price
7. Farmer Black has budgeted for next season's crop based on the same input costs over 800ha. As yields and prices can fluctuate she wants to analyse profit at different yield and price points.

Complete the following budgeting table to show:
a. The costs of growing and delivering the crop - use the table in Q3 to assist.
b. The income that may be expected at different yields and price points. (Yield x Price = Income)
c. The profit that may be expected at different price points per hectare (Yield x Price - Costs = Profit)

| Wheat Price |  | \$250/t |  | \$300/t |  | \$350/t |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Yield | Costs | Income | Profit | Income | Profit | Income | Profit |
| 1.0t/ha | 281440 | 200000 | -81440 | 240000 | -41440 | 280000 | -1440 |
| 2.0t/ha | 312480 | 400000 | 87520 | 480000 | 167520 | 560000 | 247520 |
| 3.0t/ha | 343520 | 600000 | 256480 | 720000 | 376480 | 840000 | 496,480 |
| 3.5t/ha | 359040 | 700000 | 340960 | 840000 | 480960 | 980000 | 620960 |

8. Farmer Black could put extra 30kg/ha of Nitrogen fertiliser on the crop in August. It will cost $\$ 17 /$ ha and could improve yields by $10 \%$ if it is followed by a significant rain event. Without any rain, the plant cannot uptake the nitrogen and there is no benefit. Over the last 6 years, her average yield has been $2.8 t$ and she has sold her wheat at an average price of $\$ 295 / \mathrm{t}$. Can you do a cost-benefit analysis on this scenario and recommend whether or not she should go ahead?

If average yield is $2.8 \mathrm{t} / \mathrm{h}$ a the nitrogen has the potential to add another 280 kg .
At $\$ 295 / \mathrm{t}(\$ 295$ divided by $1000 \mathrm{~kg}=0.295 \mathrm{c} / \mathrm{kg}$ ), 280 kg is worth $\$ 82.60$ The worst case scenario is there is no yield improvement and the farmer loses the $\$ 17 / \mathrm{ha}$

Best case scenario the farmer gains 10\% improvement and makes an extra \$82.60/ha

Cost for 800ha is \$13600
Benefit of up to \$66 080
The farmer will remain profitable even if there is no yield improvement so I would recommend he take the risk and add the fertiliser.

Some students may recommend that the decision be made based on weather predictions.
